**ABSTRACT**

**Background:** *Pycnanthus angolensis* (Welw.) Warb. (Myristicaceae) is a medicinal plant used in traditional Ivorian medicine. A recent ethnobotanical survey has discovered *Pycnanthus angolensis* in the traditional treatment of viral and parasitic diseases.

*Corresponding author: E-mail: kouadio777@gmail.com;*  
Aim: The present study aims to highlight the distinctive ethnopharmacological characteristics of *Pycnanthus angolensis*.

Methods: The aim was to identify some groups of chemical compounds by thin layer chromatography, to assay some minerals and finally to characterise the specific anatomical and micrographic features of the plant.

Results: Terpenes and sterols, saponosides, flavonoids and tannins are the main phytochemicals revealed. Magnesium with 621.3 mg/100 g dry matter is the most abundant mineral. Anatomical sections and plant powder revealed starch grains, calcium oxalate crystals, secretory pockets and tector hairs that are responsible for the formation of various biological substances in the plant.

Conclusion: These results add to the data on *Pycnanthus angolensis*, a taxon much used in traditional Ivorian medicine for the treatment of antiparasitic and antiviral diseases.

Keywords: *Pycnanthus angolensis*; ethnopharmacological characteristics; antiparasitic; antiviral; Côte d'Ivoire.

1. INTRODUCTION

*Pycnanthus angolensis* (Welw.) Warb. or *Pycnanthus kombo* (Baill.) Warb., commonly known as African nutmeg, is a tree species found in West and Central Africa. Different parts of the tree are traditionally used for a wide range of medicinal purposes, including the treatment of pain and fungal infections [1]. Various preparations of the bark, and other parts as well but to a lesser extent, are used in traditional medicines [2]. Topical application of the bark powder and decoction is used for skin cancer in Ghana, while decoction of its stem bark and leaves are also used for wound healing [3]. According to N’Guessan et al. [4], stem bark is used to facilitate delivery. Its chemical analysis also revealed the presence of isoflavone, terpenoid-type quinone, and cyclolignene derivatives [5] justifying various biological activities. Elsewhere, the plant is used as an analgesic, carminative, anthelmintic, anti-inflammatory, haemostatic and antimicrobial [6]. Akinyeye and Olatunya [7] reveal that *P. angolensis* is also used in the treatment of female infertility, rheumatism, sore throat and bronchopneumonia. In vitro studies by Kamanzi [8] (2002) revealed that *Pycnanthus angolensis* (stem bark) is not cytotoxic.

Recent studies have revealed its use in Côte d’Ivoire in the traditional treatment of parasitic and viral pathologies. Several studies have been carried out on *Pycnanthus angolensis*. It is important to compare all these data obtained from the plant with that found in Côte d’Ivoire. The present study aims to highlight the distinctive ethnopharmacological characteristics of *Pycnanthus angolensis*.

2. MATERIALS AND METHODS

2.1 Materials

The parts of *Pycnanthus angolensis* used were the stem bark and the young stem. The stem bark was used for phytochemistry, mineralogy and micrography. The young stem was used for anatomical-histological cross-sections. These organs were harvested on the Yakkassé-Attobrou (Adzope, Côte d'Ivoire). The geographic coordinates are 6°10'51" N and 3°39'26" W.

2.2 Methods

Phytochemistry:

This phase started with the extraction of the different phytochemicals. The plant powder was introduced into a 50 mL Falcon tube and cold macerated for 24 hours in the extraction solvent (96% ethanol). The filtrate obtained was used for phytochemical screening.

Phytochemical screening of the extracts was performed on HPTLC plates (20 cm × 10 cm) silica gel 60 F 254 (Merck, Darmstadt, Germany).

10 µL of extract were deposited in a 1 cm strip with a semi-automatic sample dispenser (CAMAG, Linomat 5, Switzerland) along the baseline 8 mm from the bottom edge of the plate. The distance between the spots is 3.4 mm. The distance between the first spot and the left edge of the plate and between the last spot and the right edge of the plate is 20 mm. A constant application rate of 100 nL/s was used. Linear upward development with 10 mL mobile phase
was performed in a CAMAG double-trough glass chamber lined with filter paper and previously saturated with mobile phase vapour for 20 minutes. The development distance was approximately 70 mm. The plates were dried after development using a hair dryer. In the double trough chamber, the mobile phases were:

- Terpenoids, eluted with hexane/ethyl acetate system 20:4, v/v and revealed by Liebermann Bürchard reagent;
- Saponosides, eluted with ethyl acetate/petroleum ether 2:1, v/v revealed with sulphuric anisaldehyde;
- Flavonoids and tannins: ethyl acetate/formic acid/acetic acid/water 100:11:11:26, v/v/v. Flavonoids were revealed by Neu's reagent, tannins by \( \text{FeCl}_3 \) (2 %).

**Mineralogy:**

For the determination of mineral elements, the Analist Pinaacle 900T air-acetylene flame atomic adsorption spectrometer (Perkin Elmer) was used. The wavelengths of the elements to be analysed were first defined on the instrument (324.75 nm for copper, 213.86 nm for zinc, 248.33 nm for iron, 285.2 nm for magnesium, 766.49 nm for potassium, 279.48 nm for manganese and 589.0 nm for sodium). Then, the different readings of the calibration ranges were used to establish the calibration curve translating absorbance as a function of concentration. Finally, the samples to be analysed were presented to the apparatus in order to determine their absorbances. A blank is necessarily passed between the passage of two different solutions.

**Anatomo-histology:**

It consisted of making thin cross-sections of a portion of *Pycnanthus angolensis* stem using a new razor blade. The stem was inserted into sorghum or polystyrene pith. The whole set of sections was soaked in diluted bleach for 20 min followed by rinsing with plain water. The sections were then soaked in acetic water for 15 minutes to neutralise the excess bleach, which is chemically basic and makes the cell walls receptive to the dye. After this step, the sections obtained were stained with carmino-green (a mixture of carmine alumina and iodine green) and then rinsed one last time with water. Thus, the cell walls were stained according to their chemical nature (cellulosic walls in pink and lignified walls in green). The stained sections were then mounted between slides and coverslips in a drop of glycerine water for observation under a photonic microscope connected to a computer. After observation, the different sections were photographed.

**Micrography:**

On an object slide, a drop of 10% potash was placed. This preparation was sprinkled with a pinch of fine plant drug powder obtained using a 500 μm mesh sieve. This was covered with a slide without leaving any air bubbles. The powder thus treated was observed with an Optika Microscopes Italy photonic microscope, connected to a tablet. Observations were made at x40 and x100 magnification in order to look for characteristic elements or organ fragments. These observed elements were then photographed.

### 3. RESULTS AND DISCUSSION

**Systematic position:**

Kingdom: Plantae
Clade: Angiosperms
Clade: Dicotyledons
Order: Magnoliales
Family: Myristicaceae
Genus: *Pycnanthus*
Species: *Pycnanthus angolensis* (Welw.) Warb.

**Synonyms:**

- *Myristica angolensis* Welw.
- *Pycnanthus kombo* (Baill.) Warb
- *Pycnanthus microcephalus* (Benth.) Warb.

**Common names:** Iromba, Tallow Tree, White Cedar, Wild Muscat.

**Local names:** Etrain (Baoulé), Dign (Yacouba), Iromba (Guéré), Guilo (Attié), Tiè (Brong).

**Herbarium specimen number:**

CSRS: N°10-CSRS004841-A4-C88-R1-E4-F4-P1

**Botanical description:**

*Pycnanthus angolensis* is an evergreen, monoecious or dioecious, medium to large tree reaching 25-35(-40) m tall; bole generally straight and cylindrical, branchless to 15(-25) m tall, up to 120(-150) cm in diameter, generally lacking...
buttresses; outer bark greyish brown, with orange-brown exudate; crown small, with branches perpendicular to bole. The leaves are alternate distichous, simple and entire (Fig. 1A); the blade is oblong to oblong-lanceolate with a cordate base; the apex is acuminate, dark green above, glaucous below. The young leaves are velvety with reddish brown hairs, but glabrescent, pinnately veined with 20-40 pairs of lateral veins. The inflorescence is an axillary panicle, often on leafless twigs, red-hairy, with flowers in numerous padded clusters. Flowers unisexual, regular, very small, sessile, with a 3-lobed perianth covered with dark brown hairs; male flowers with 2-4 stamens, threads fused into a column; female flowers with a superect ovary, sessile, 1-locular, stigmas 2, sessile. The fruit is an ellipsoid to oblong or globose drupe, clustered, yellowish orange at maturity, fruit wall rather hard and leathery, splitting longitudinally by 2 valves, containing 1 seed (Fig. 1B). The seed is ellipsoid, aromatic, dark brown, with a pink to red aril, laciniated almost to the base [9,10].

Habitat and geographical distribution:

*Pycnanthus angolensis* (Welw.) Warb. (Myristicaceae) is widely disturbed in the tropical Africa (Fig. 2). Its phytogeographical distribution is Guinean-Congolese [11]. *P. angolensis* is a widespread species in secondary forests. It immediately repopulates old abandoned clearings.

Traditional uses in Côte d'Ivoire in the treatment of parasitic and viral diseases:

The exudate of the trunk applied as an eye instillation treats Onchocerciasis. Against Schistosomiasis, the decoction of the stem bark is taken as a drink. The same beverage is prescribed as a drink against HIV/AIDS and other viral pathologies. Several phytomolecules extracted from *Pycnanthus angolensis* have antiviral and antiparasitic activities [12].

**Other therapeutic uses:**

The stem bark of *Pycnanthus angolensis* is recommended for the treatment of infectious diseases. The exudate is indicated against gingivitis and the stem is used to clean the teeth.

Krief [13] confirmed the latter use. The decoction of the stem bark is prescribed against viral diseases. The antimicrobial effects of *Pycnanthus angolensis* [14]. En outre, some research shows a wide range of biological activities, including antioxidant, antiviral, anti-inflammatory, antibacterial, antiallergic, hepatoprotective, cytotoxic, estrogenic, antiestrogenic and pro-apoptotic [1, 15, 16, 17, 18, 19, 20].

The exudate is used cutaneously against skin diseases (scabies, chickenpox, leprosy) [21].

**Phytochemistry:**

The chromatogram (Fig. 3) shows the phytochemical composition of the stem bark of *Pycnanthus angolensis*. The presence of terpenes and sterols, saponosides, flavonoids and tannins is observed. These same phytocompounds have been highlighted by some authors [14, 22, 23, 24, 25].

**Mineralogy:**

Table 1 shows the mineralogical composition of the stem bark of *Pycnanthus angolensis*. The amount of magnesium is 621.3 mg/100 g dry matter. It is the most abundant mineral. Ngbolua et al. [26] determined Mg (0.04±0.002 %MS) and Fe (0.007±0.002 %MS).

**Anatomy:**

Fig. 4 shows a cross-sectional portion of a *Pycnanthus angolensis* stem. From the periphery to the centre of the organ, epidermis, collenchyma, cortical parenchyma, phloem, xylem and medullary parenchyma can be seen. Jackson and Snowdon [27] observed the same tissues in other Myristicaceae. Schizogenic secretory pockets and calcium oxalate crystals are also seen. Indeed, a calcium deposit is observed in a container containing latex taken from the trunk of *P. angolensis*. Secretory pockets are cavities in the parenchyma of the *P. angolensis* stem. These cavities are lined with cells that excrete products that they have synthesised.

**Micrography:**

Microscopic observation of *Pycnanthus angolensis* powder identified starch grains, calcium oxalate crystals and tector hairs (Fig. 5). Oxalate (1.46 g/100 g) and carbohydrates (0.92 mg/g) including starch grains were measured in some parts of *Pycnanthus angolensis*. Udeozo et al. [22]. Furthermore, studies have shown that the Myristicaceae family, particularly in the species *Myristica fragrans*, contains abundant starch grains and crystals [27].

**4. CONCLUSION**

The study identified the distinctive ethnopharmacological characteristics of *Pycnanthus angolensis* (Fabaceae). Starch grains, calcium oxalate crystals, secretory pockets, and tector hairs were observed. Furthermore, the phytochemical and mineralogical composition would justify the use of *Pycnanthus angolensis* in the traditional treatment of lymphatic filariasis.
